

Abstract

of DE G 87 06 358.1

X-ray device having a telescope made of several telescopeable tubes, which is connected via a first cable with a device for the compensation of weight. The device for the compensation is comprises a spiral winch for a winding and unwinding the first cable, where a radius of the spiral winch decreases with an increasing pressure of a spring so that a force compensating the weight remains a essentially constant regardless of the particular length of the telescope.
